Description of Related Art In modern integrated circuits (ICs), especially very large scale integrated circuits (VLSIs), metal-oxide-semiconductor field effect transistors (MOSFETs) made from Si (silicon) are the basic building blocks. Advances in Si-based technology have enabled the integration of thousands of the MOSFETs on a single Si chip. However, the scaling of MOSFET dimensions to the deep submicron range poses great challenges in maintaining performance. High dielectric constant (high-k) dielectrics such as high-k dielectric metal oxide layers are gaining attention as replacements for SiO2 in the formation of intermetal dielectrics (IMDs), because of their lower leakage current and ability to prevent short channel effects. High-k dielectric metal oxide layers include HfO2 (hafnium oxide), ZrO2 (zirconium oxide), ZrSiO2 (zirconium silicate), ZrO2HfO2 (zirconium oxide-hafnium oxide), Al2O3 (aluminum oxide) and Sc2O3 (scandium oxide). The metallic contaminants in the high-k dielectric material can be difficult to remove because of the low chemical reactivity of high-k materials. There is a need for an improved method of
